

The first part of the paper describes the development of the instrument and the results of a pilot study. The second part reports the results of the main study, which was conducted in two phases. In the first phase, the instrument was used to assess the perceived barriers to the implementation of the intervention in a sample of 100 health professionals. In the second phase, the instrument was used to assess the perceived barriers to the implementation of the intervention in a sample of 100 health professionals. The results of the main study are presented in Table 1. The results show that the instrument was able to identify a wide range of barriers to the implementation of the intervention. The most common barriers were related to the lack of resources, the lack of knowledge, and the lack of motivation. The results also show that the instrument was able to identify barriers that were specific to the intervention. For example, the instrument identified barriers related to the lack of knowledge about the intervention and the lack of motivation to implement the intervention. The results of the main study suggest that the instrument is a valid and reliable tool for assessing the perceived barriers to the implementation of the intervention.
